Analysis and Optimization for Weighted Sum Rate in Energy Harvesting Cooperative NOMA Systems

Binh Van Nguyen, Quang-Doanh Vu, and Kiseon Kim

Abstract—We consider a cooperative non-orthogonal multiple access system with radio frequency energy harvesting, in which a user with good channel harvests energy from its received signal and serves as a decode-and-forward relay for enhancing the performance of a user with poor channel. We here aim at maximizing the weighted sum rate of the system by optimizing the power allocation coefficient used at the source and the power splitting coefficient used at the user with good channel. By exploiting the specific structure of the considered problem, we propose a low-complexity one-dimensional search algorithm which can provide optimal solution to the problem. As a benchmark comparison, we derive analytic expressions and simple high signal-to-noise ratio (SNR) approximations of the ergodic rates achieved at the two users and their weighted sum with fixed values of the power allocation and the power splitting coefficients, from which the scaling of the weighted sum in the high SNR region is revealed. Finally, we provide representative numerical results to demonstrate the validity of our results.

Index Terms—Cooperative NOMA, RF-energy harvesting, weighted sum rate analysis and optimization.

I. INTRODUCTION

Non-orthogonal multiple access (NOMA) transmission is emerging as a promising multiple access technique for the next generation of wireless networks [1]. The cornerstone of NOMA is to exploit the power domain and channel quality difference among users to achieve multiple access. An issue rising in a NOMA system is that users with good channel conditions can significantly strengthen the performance, while the performance of users with bad channel conditions are relatively poor [2]. A possible solution for this problem is combining cooperative communication with NOMA to generate a cooperative NOMA (C-NOMA) transmission scheme in which users with good channel conditions operate as relays to strengthen the transmission reliability for users suffering from bad channel conditions [3]-[6].

Recently, radio frequency energy harvesting (RF-EH) has become an efficient solution to prolong the lifetime of energy-constraint wireless communication systems [7]. The advantage of RF-EH is from the fact that RF signals carry both information and energy at the same time, i.e. RF-EH allows limited-power nodes to scavenge energy and process information simultaneously [8]. There exist two main RF-EH techniques, namely, time switching (TS) and power splitting (PS). With TS, a receiver switches between energy harvester and data decoder. With PS, a receiver separates the RF signals into two parts (one for EH and the other for decoding) by a PS coefficient. Here, we mainly focus on PS, since PS is considered to be more general compared to TS [9]. In C-NOMA systems, in some cases due to the limited energy at good users, i.e. in sensors and internet-of-things contexts, it may not be possible for good users to relay signals toward poor users. To alleviate this issue, RF-EH is introduced to C-NOMA systems. Representative examples for this approach are [10]-[12]. Particularly, [10]-[11] proposed user-pair selection schemes and analyze the performance in terms of outage probability. In addition, [12] investigated the problem aiming at maximizing the achievable rate of a good user while guaranteeing the quality-of-service requirement of a poor user.

Different from [10]-[12], in this work, we focus on maximizing weighted sum rate of an RF-EH C-NOMA system which has been still relatively open. It is worth mentioning that the problem of weighted sum rate allows to prioritize users, and thus, finds many applications in wireless communications [13]-[14]. For examples, the weights can be chosen by the controller (i.e. scheduler) based on the state of the packet queues following the max-stability policy (please refer to [14] for detail discussion); or the controller determines the weights based on the throughput for the users in the previous time slots for, e.g. proportional fairness [15]. Also, the weighted sum rate problem is encountered in network utility maximization and cross-player control policies [16]. It should be noted that the results presented in [12] cannot be directly applied to our problem due to the different structures of the two problems. Specifically, our main contributions are as
follows.

- We consider an RF-EH C-NOMA system having a source and two users. We formulate the problem of weighted sum rate maximization in which power allocation (PA) and PS coefficients are the design parameters. The problem is non-convex whose optimal solution can be found by the exhaustive two-dimensional (2D) search. Towards a more efficient solution, we develop an one-dimensional (1D) search algorithm by exploiting the specific structure of the problem.
- For a comparison benchmark, we derive closed-form expressions and high signal-to-noise ratio (SNR) approximations of the ergodic rates achieved at the two users and their weighted sum with fixed PA and PS coefficients.
- We numerically demonstrate that optimized PA and PS coefficients can significantly improves the system performance in terms of weighted sum rate, i.e. 37.5% enhancement when the average SNR is 30 dB and the weight ratio is 5. On the other hand, the analysis results reveal that the scaling of the weighted sum rate is $\frac{w_1}{2} \log_2 (SNR)$, where $w_1$ is the priority weight of the good user.

II. System Model

We consider a wireless communication system consisting of a source, denoted by $S$, and two users which are associated with different channel conditions; we denote the user with good channel by $U_1$, and the one with bad channel by $U_2$. All nodes are equipped with a single-antenna and operate in the half-duplex mode. Let $h_1$, $h_2$, and $h_3$ denote the channel complex coefficients between $S$ and $U_1$, $S$ and $U_2$, and $U_1$ and $U_2$, respectively. All channels are assumed to be independent and identically distributed Rayleigh block fading. From the assumption about channel quality, we have $g_1 \geq g_2$ where $g_i = |h_i|^2$.

We focus on the transmission from $S$ to the users. The transmission protocol includes two phases, each of length $T$ in time unit. In particular, let $x_i$, $i \in \{1, 2\}$, be the normalized complex signal for $U_i$, and $P_S$ be the transmit power at $S$. In the first phase, $S$ generates a superimposed signal given by $x_S = \sqrt{\alpha P_S} x_1 + \sqrt{(1-\alpha) P_S} x_2$, where $\alpha$ denotes the PA coefficient, and broadcasts $x_S$ to the users. The received signal at $U_i$ during this phase is

$$y_i = h_i x_S + n_i$$

where $n_i$ is the additive white Gaussian noise (AWGN) with variance $N_0$ at the note $U_i$.

User $U_1$ uses its received signal for decoding $x_1$, harvesting energy, and decoding $x_2$. In particular, $U_1$ divides $y_1$ into two parts with a PS coefficient $\rho \in [0, 1]$. The first part given by $y_1^h = \sqrt{\rho} y_1$ is for harvesting energy, and the second part given by $y_1^{ip} = \sqrt{1-\rho} y_1$ is for decoding information. Consequently, the energy harvested at $U_1$ is [11]

$$E_1 = T \eta \rho P_S g_1$$

where $\eta$ denotes the energy conversion efficiency. $U_1$ decodes $x_2$ based on $y_1^{ip}$, then applies successive interference cancellation (SIC) before decoding $x_1$. Therefore, the signal-to-interference-plus-noise ratios (SINRs) for decoding $x_2$ and $x_1$ at $U_1$ are as follows

$$\gamma_1^{x_2}(\alpha, \rho) = \frac{(1 - \rho)(1 - \alpha) P_S g_1}{(1 - \rho) \alpha P_S g_1 + (1 - \rho) N_0 + \mu N_0}, \quad (3)$$

$$\gamma_1^{x_1}(\alpha, \rho) = \frac{(1 - \rho) \alpha P_S g_1}{(1 - \rho) N_0 + \mu N_0}, \quad (4)$$

respectively. Here, the last term in the denominator of $\gamma_1^{x_2}(\alpha, \rho)$ and $\gamma_1^{x_1}(\alpha, \rho)$ are due to the conversion noise which is assumed to be AWGN with variance $\mu N_0$ [17].

In the second phase, $U_1$ uses the harvested energy $E_1$ to transmit $x_2$ to $U_2$. The signal received at $U_2$ during this phase is

$$\hat{y}_2 = \sqrt{\rho \eta P_S g_1} b x_2 + n_2,$$

where we, following recent related works, have assumed that the harvested energy is used for information forwarding only, while the energy for maintaining circuit and signal processing is neglected [10]-[12]. We suppose that the maximal ratio combining (MRC) receiver is used at $U_2$ [18]. Then the SINR for decoding $x_2$ at $U_2$ is

$$\gamma_2^{MRC}(\alpha, \rho) = \frac{(1 - \alpha) P_S g_2}{\alpha P_S g_2 + N_0 + \mu N_0 + \rho \eta P_S g_1 g_3}, \quad (6)$$

In summary, the instantaneous achieved rates at $U_1$ and $U_2$ are $C_1(\alpha, \rho) = \frac{1}{2} \log_2 (1 + \gamma_1^{x_1}(\alpha, \rho))$ and $C_2(\alpha, \rho) = \frac{1}{2} \log_2 (1 + \min \{\gamma_2^{x_2}(\alpha, \rho), \gamma_2^{MRC}(\alpha, \rho)\})$, respectively.

III. Weighted Sum Rate Optimization

Our aim is to maximize the weighted sum rate of the system. Particularly, the optimization problem is formulated as

$$\max_{\alpha, \rho} w_1 C_1(\alpha, \rho) + w_2 C_2(\alpha, \rho) \quad (7a)$$

subject to $0 < \alpha < 1, 0 \leq \rho \leq 1, \quad (7b)$

where $w_1 > 0$ and $w_2 > 0$ are the priority weights. Here we focus on the case $w_2 > w_1$ since the optimal solution for the case $w_2 \leq w_1$ is trivial, i.e. it is not difficult to justify that the optimal solution for this case is $(\alpha = 1, \rho = 0)$. A practical example for the considered scenario is that in cellular network, the user at cell-edge suffering bad channel conditions for a long time will be assigned a larger weight compared to the one in near base station area for fairness and/or stability [13]-[14].

Objective function (7a) is non-convex with respect to the related variables. For achieving an optimal solution, an exhaustive 2D search procedure (over $\alpha$ and $\rho$) can be used. Clearly, doing this is highly complex and inefficient. In the following, by looking inside the problem, we develop a low-complexity 1D search algorithm which solves (7) optimally.

1The weights are the given parameters which is determined by the controllers for a specific policy, e.g. buffer stability or proportional fairness.
We start with an useful result stated as follows.

**Lemma 1.** Let \( (\alpha^*, \rho^*) \) be an optimal of (7), then

\[
C_2 (\alpha^*, \rho^*) = \frac{1}{2} \log_2 \left( 1 + \gamma^{\text{MRC}}_2 (\alpha^*, \rho^*) \right). \tag{8}
\]

**Proof:** The lemma can be proved by contradiction, i.e. we first assume that there is an optimal point such that (8) does not hold then we show that the point does not exist. More specifically, suppose that there exists an optimal point \((\alpha^*, \rho^*)\) such that

\[
\log_2 \left( 1 + \gamma^2_1 (\alpha^*, \rho^*) \right) < \log_2 \left( 1 + \gamma^{\text{MRC}}_2 (\alpha^*, \rho^*) \right). \tag{9}
\]

Clearly, it must be \( \rho^* > 0 \) due to the assumption \( g_1 \geq g_2 \). Now, we observe that \( \gamma^{\text{MRC}}_2 (\alpha, \rho) \) and \( \gamma^2_1 (\alpha, \rho) \) are increasing and decreasing functions of \( \rho \), respectively. And \( \gamma^2_1 (\alpha, 0) > \gamma^{\text{MRC}}_2 (\alpha, 0) \). Consequently, we always can find \( \Delta \rho > 0 \) such that \( \rho^* - \Delta \rho \geq 0 \), and \( \gamma^2_1 (\alpha^*, \rho^* - \Delta \rho) = \gamma^{\text{MRC}}_2 (\alpha^*, \rho^* - \Delta \rho) \). Since \( \gamma^2_1 (\alpha^*, \rho^* - \Delta \rho) > \gamma^2_1 (\alpha^*, \rho^* \) we have \( C_2 (\alpha^*, \rho^* - \Delta \rho) > C_2 (\alpha^*, \rho^* \) Moreover, \( C_1 (\alpha^*, \rho^* - \Delta \rho) > C_1 (\alpha^*, \rho^* \) because \( \gamma^1_1 (\alpha, \rho) \) is a decreasing function of \( \rho \). Consequently, we have \( w_1 C_1 (\alpha^*, \rho^* - \Delta \rho) + w_2 C_2 (\alpha^*, \rho^* - \Delta \rho) > w_1 C_1 (\alpha^*, \rho^*) + w_2 C_2 (\alpha^*, \rho^* \). This means the point \((\alpha^*, \rho^* - \Delta \rho)\) achieves a better objective value compared to \((\alpha^*, \rho^* \), which contradicts the assumption at the beginning of the proof that \((\alpha^*, \rho^* \) is an optimal. This implies that, at the optimal, we always have \( \log_2 (1 + \gamma^2_1 (\alpha^*, \rho^*)) \geq \log_2 (1 + \gamma^{\text{MRC}}_2 (\alpha^*, \rho^*)) \). This completes the proof.

From Lemma 1 and the monotonicity of the logarithmic function, we can rewrite (7) as

\[
\max_{\alpha, \rho} \frac{f(\alpha, \rho)}{\rho} \tag{10a}
\]

subject to

\[
\gamma^2_1 (\alpha, \rho) \geq \gamma^{\text{MRC}}_2 (\alpha, \rho), \tag{10b}
\]

\[
0 < \alpha < 1, 0 \leq \rho < 1 \tag{10c}
\]

where \( f(\alpha, \rho) \triangleq (1 + \gamma^2_1 (\alpha, \rho)) \left( \gamma^{\text{MRC}}_2 (\alpha, \rho) \right)^{\tilde{w}_2} \), and \( \tilde{w}_2 = w_2 / w_1 \). As a further step, we equivalently rewrite (10) as

\[
\max_{\alpha, \rho} \frac{f(\alpha, \rho)}{\rho} \tag{11a}
\]

subject to

\[
0 < \alpha < 1, 0 \leq \rho < \tilde{\rho}(\alpha), \tag{11b}
\]

where \( \tilde{\rho}(\alpha) = \frac{1 - \sqrt{1 - 4ac}}{2b} \). If \( \gamma = P_2 / N_0, \ a = 2 \tilde{\gamma}_g \tilde{\gamma}_1 (\tilde{\gamma}_g + 1) \), \( b = \tilde{\gamma}_g \tilde{\gamma}_1 (\tilde{\gamma}_g + 1) / (1 - \tilde{\alpha} \tilde{\gamma}_g (\tilde{\gamma}_g + 1)) \), \( c = (1 - \tilde{\alpha}) \tilde{\gamma}_g - (1 - \alpha) \tilde{\gamma}_g \tilde{\gamma}_1 (\tilde{\gamma}_g + 1) \tilde{\gamma}_g + (1 - \alpha) \tilde{\gamma}_1 \), and \( \tilde{\gamma}_1 = 1 - \tilde{\gamma}_g \tilde{\gamma}_1 (\tilde{\gamma}_g + 1) \). The equivalence can be proved as follows. We first note that the left hand-side (LHS) of (10b) monotonically increases while the right hand-side (RHS) of (10b) monotonically decreases with \( \rho \). In addition, when \( \rho = 0 \), the RHS is larger than the LHS due to the assumption \( g_1 \geq g_2 \). Moreover, the RHS \( \rightarrow 0 \) when \( \rho \rightarrow 1 \). Thus, given \( \alpha \in (0, 1) \), there exists an unique \( \tilde{\rho}(\alpha) \in (0, 1) \) such that (10b) is satisfied if and only if \( \rho \in [0, \tilde{\rho}(\alpha)] \). It is noting that (10b) can be written as \( a\rho^2 - b\rho + c \geq 0 \), from which we yield \( \tilde{\rho}(\alpha) \). The new bound \( \tilde{\rho}(\alpha) \) in (11b) plays the important role in developing the proposed algorithm.

\section{IV. Ergodic Rate Analysis}

In this section, we derive the ergodic rates achieved at the users (and their weighted sum) with fixed values of \( \alpha \) and \( \rho \), which can be used as a benchmark in evaluating the Algorithm 1.

Before going into detail, it is important to note that the cumulative distributed function (CDF) of the ordered variables \( g_1 \) and \( g_2 \) are given by \( F_{g_1}(x) = F_{g_1}(x) F_{g_2}(x) \) and \( F_{g_2}(x) = 1 - [1 - F_{g_1}(x)] [1 - F_{g_2}(x)] \), where \( F_{g_1}(x) \) and \( F_{g_2}(x) \) are the CDF of unordered variables \( g_1 \) and \( g_2 \).
A. Ergodic Rate of $U_1$

The ergodic rate of the $U_1$ is expressed as follows [18]

$$C_1^e = \frac{1}{2 \ln(2)} \int_0^\infty \frac{1 - F_X(x)}{1 + x} dx,$$

where $X = \frac{(1 - \rho)\alpha \epsilon g_1}{\sigma + \mu}$, and $F_X(x)$ is given by

$$F_X(x) = 1 - \sum_{i=1,2} \exp\left(-\frac{Ax}{\delta_i^2}\right) + \exp\left(-\frac{Ax}{\delta_{12}^2}\right),$$

where $\delta_i^2 = d_i^{-\epsilon_i}$ is the power of the unordered channel $\tilde{h}_i$, $d_i$ and $\epsilon_i$ denote the distance and the pathloss exponent, $\delta_{12}^2 = \delta_1^2 \delta_2^2 / (\delta_1^2 + \delta_2^2)$, and $A = (1 - \rho + \mu) / (1 - \rho) \alpha^\gamma$. Plugging (16) into (15) gives

$$C_1^e = \frac{1}{2 \ln(2)} \sum_{i=1,2} \psi(i) \exp\left(\frac{A}{\delta_i^2}\right) \Gamma\left(0, \frac{A}{\delta_i^2}\right),$$

where $\psi(1) = 1$, $\psi(2) = 1$, $\psi(12) = -1$, and $\Gamma(x, y)$ is the incomplete upper Gamma function.

B. Ergodic Rate of $U_2$

Similar to (15), we have

$$C_2^e = \frac{1}{2 \ln(2)} \int_0^\infty \frac{1 - F_Z(z)}{1 + z} dz,$$

where $Z = \min\{\gamma_1^2(\alpha, \rho), \gamma_2^\text{MRC}(\alpha, \rho)\} = \min\{Y, W\}$ and $F_Z(z)$ can be approximated as

$$F_Z(z) \approx 1 - \text{Pr}[Y > z] \text{Pr}[W > z],$$

where the correlation between $Y$ and $W$ is ignored. It can be readily verified that the correlation between $Y$ and $W$ vanishes in the high SNR region implying that the approximation is tight when the average SNR goes large. The probability term $\text{Pr}[Y > z]$ is first derived as

$$\text{Pr}[Y > z] = \left\{\begin{array}{ll}
0, & \text{if } z \geq \frac{1 - \alpha}{\alpha}, \\
\sum_{i=1,2} \psi(i) \exp\left(-\frac{\alpha Az}{\delta_i^2(1 - \alpha - \alpha z)}\right), & \text{if } z < \frac{1 - \alpha}{\alpha}.
\end{array}\right.$$  

(20)

Secondly, $\text{Pr}[W > z]$ can be approximated as follows

$$\text{Pr}[W > z] \approx 1 - \int_0^z F_W(z - y) f_{W_2}(y) dy,$$

where $W_1 = \frac{(1 - \alpha)\gamma g_2}{\sigma + \mu}$ and $W_2 = \frac{\gamma g_2}{\sigma + \mu}$, and

$$F_W(z) = \left\{\begin{array}{ll}
1, & \text{if } z \geq \frac{1 - \alpha}{\alpha}, \\
1 - \exp\left(-\frac{\alpha z}{\gamma g_2(1 - \alpha - \alpha z)}\right), & \text{if } z < \frac{1 - \alpha}{\alpha},
\end{array}\right.$$  

(22)

$$f_{W_2}(y) = 2 \sum_{i=1,2} \psi(i) \frac{B}{\delta_i^2} K_0\left(2 \sqrt{\frac{B z}{\delta_i^2}}\right),$$

(23)

where $B = (1 + \mu) / (\rho g_2 \delta_3^2)$ and $K_n(x)$ denotes the modified Bessel function of the second kind of order $n$th [19]. Plugging (20) and (21) into (19), we obtain

$$C_2^e \approx \frac{1}{2 \ln(2)} \int_0^z \frac{1}{1 + z} \sum_{i=1,2} \psi(i) \sqrt{\frac{B z}{\delta_i^2}} K_0\left(2 \sqrt{\frac{B z}{\delta_i^2}}\right) dz,$$

(24)

which can be readily evaluated by using Matlab or Mathematica. From (17) and (26), we can straightforwardly obtain the system weighted sum rate, i.e. $C_{\text{sum}}^e = w_1 C_1^e + w_2 C_2^e$, with fixed values of $\alpha$ and $\rho$.

C. High SNR Analysis

To gain novel insights from our afore-presented analytic results, we now investigate the ergodic rates in the high SNR region.

**Proposition 2.** In the high SNR region, the ergodic rates of $U_1$ and $U_2$ can be approximated as follows

$$C_1^e \approx \frac{1}{2 \ln(2)} \left[\ln \left(\frac{\delta_1^2 + \delta_2^2}{A}\right) - \chi\right],$$

(27)

$$C_2^e \approx \frac{1}{2 \ln(2)} \left[\ln \left(\frac{\delta_1^2 + \delta_3^2}{A}\right) - \chi\right],$$

(28)

where $\chi$ denote the Euler constant.

**Proof:** For $C_1^e$, we first note that $\Gamma(0, x) = -Ei(-x)$, where $Ei(x)$ denotes the exponential integral function. Then using the the facts that $\exp(x) \xrightarrow{\alpha \rightarrow 0} 1$ and $Ei(x) \xrightarrow{x \rightarrow \infty} \chi + \ln(-x) + x$, we can obtain (27). For $C_2^e$, let’s first recall its instantaneous expression $C_2 = \frac{1}{2 \ln(2)} \left[\ln \left(\frac{\delta_1^2 + \delta_2^2}{A}\right) - \chi\right]$. Then, in the high region of $\gamma$, we can readily show that $\gamma_1^2(\alpha, \rho) \rightarrow \frac{1 - \alpha}{\alpha}$ and $\gamma_2^\text{MRC}(\alpha, \rho) \rightarrow \frac{1 - \alpha}{\alpha} + \rho g_2 \delta_3^2 / (\sigma + \mu)$, from which (28) can be obtained.
Proposition 2 implies that as the average SNR $\bar{\gamma}$ increases, the ergodic rate of $U_1$ monotonically increases, however, that of $U_2$ is saturated. This is reasonable because as $\bar{\gamma}$ increases, the SNR used for decoding $x_1$ at $U_1$ also increases, and thus, the ergodic rate of $U_1$ increases. On the other hand, the actual SINR used for decoding $x_2$ is limited by the minimum of the SINRs used for decoding $x_2$ at $U_1$ and $U_2$. In addition, when $\bar{\gamma}$ increases, the SINR used for decoding $x_2$ at $U_1$ quickly converges to $\frac{1}{2 \epsilon_1}$ and limits the actual SINR used for decoding $x_2$, which makes the ergodic rate of $U_2$ saturated.

From Proposition 2, we have

$$C_{\text{sum}}^e = w_1 C_1^e + w_2 C_2^e \approx \frac{w_1}{2} \log_2 (\bar{\gamma}),$$  

which reveals that when $\bar{\gamma} \to \infty$, the scaling of the system weighted sum rate is $\frac{w_1}{2} \log_2 (\bar{\gamma})$. In other words, (29) shows that the weighted sum rate increases log-linearly with the increase of the average SNR $\bar{\gamma}$.

V. Numerical Results and Discussions

We now provide representative simulated results to validate our analysis and demonstrate the enhancement of the system performance achieved by the proposed 1D algorithm. In our simulations, we set $\eta = 0.7$, $\epsilon_1 = 3$, $T = 1$, and the coordinates of source, good user, and poor user are $(0,0)$, $(1,1)$, and $(3,0)$, respectively.

Figure 1 plots the ergodic rates of the considered system with fixed values of $\alpha$ and $\rho$. The first observation is that the analytic curve of $C_1^e$ follows the corresponding simulated one excellently, while the analytic curves of $C_2^e$ and $C_{\text{sum}}^e$ quickly converge to the corresponding simulated curves in the medium and high SNR regions. This result implies that our analyses on the system’s ergodic rates are valid. Secondly, the figure confirms our finding on the scaling of the weighted sum rate in the high SNR region. The other interesting observation is that the ergodic rate of $U_2$ is saturated as the average SNR gets large, revealing that increasing the average SNR (or equally increasing the transmit power $P_3$) cannot enhance the performance of the user with poor channel.

Figure 2 plots the system weighted sum rates with optimal and fixed values of $\alpha$ and $\rho$ as functions of the average SNR. We take $\tilde{w}_2 = \{2, 5\}$. The figure clearly shows that using the Algorithm 1 remarkably enhances the weighted sum rate of the system. Particularly, at $\bar{\gamma} = 30$ dB, optimal values of $\alpha$ and $\rho$ provides 37.5% and 18.4% weighted sum rate enhancements with $\tilde{w}_2 = 5$ and $\tilde{w}_2 = 2$. Thus, the results strongly suggest that the parameters $\alpha$ and $\rho$ should be optimized.

In Fig. 3, we illustrate the average of the optimal values of $\alpha$ and $\rho$ (i.e. $\mathbb{E}\{\alpha^*\}$ and $\mathbb{E}\{\rho^*\}$, respectively) versus $\tilde{w}_2$. An interesting observation is that as $\tilde{w}_2$ increases, $\mathbb{E}\{\alpha^*\}$ reduces and approaches zero. This is due to the fact that when $\tilde{w}_2$ enlarges, $U_2$ has a higher priority compared to $U_1$, and thus, more power should be allocated to the transmission of $x_2$. On the other hand, we can also observe that $\mathbb{E}\{\rho^*\}$ increases and tends to a certain value. This is because the rate of $U_2$ provided in Lemma 1 is an increasing function with $\rho$, and $\rho^*$ should be small enough.
so that the constraint (10b) is satisfied.

VI. CONCLUSION

We considered a C-NOMA system with RF-EH including a source and two users. We first developed a 1D search algorithm to optimally solve the problem of weighted sum rate maximization respect to the power allocation \( \alpha \) and the power splitting coefficient \( \rho \). Then, we derived closed-form expressions and high SNR approximations of the ergodic rates achieved at the two users with fixed values of \( \alpha \) and \( \rho \). The numerical results demonstrated that using the optimal values of \( \alpha \) and \( \rho \) significantly enlarges the system weighted sum rate, i.e. 37.5% enhancement when the average SNR is 30 dB and the weight ratio is 5. In addition, we revealed that the scaling of the weighted sum rate with fixed value of \( \alpha \) and \( \rho \) is \( \frac{2}{\rho} \log_2(\bar{\gamma}) \) in the high SNR region.
